Follow-up: A collections score is not a licence to contact more people

Team,

Before this becomes another standing report, can we answer the real question?

Collections wants a prioritisation model, but validation must separate default risk from the effect of different contact strategies. The possible stories are that high-risk customers need tailored arrangements rather than more attempts, that contact channel changes promise-kept rates, or that some customers self-cure without intervention.

This has returned because the previous answer was useful but not strong enough to become a standing rule. Use September 2022 as the new evidence point rather than recycling the earlier conclusion. Several teams are reporting more failed or retried activity than they expected, but they do not agree on the cause.

Please prepare a short decision pack with no more than five slides and an attached evidence table. The output must help us decide whether a model can support treatment allocation and what experiment is needed next.

Data available: collections cases, promises to pay and recovery payments; customer contacts, complaints and suggestions; transaction-level timestamps, channels, amounts, statuses and error context; the latest closed loan files available by the request date, including affordability, pricing and origination risk fields.

Please state the limitation plainly: Observational data cannot prove treatment causality; recommend a controlled test where appropriate.

Thanks
