Which fraud alerts are actually operational noise? - 2023 control review

Team,

Before this becomes another standing report, can we answer the real question?

Investigators report that some suspicious patterns disappear once transaction timing, retries and customer contacts are reconstructed. The possible stories are that repeated attempts inflate velocity, that a known service interaction explains the change, or that bank-side delay creates impossible sequences.

This has returned because the previous answer was useful but not strong enough to become a standing rule. Use April 2023 as the new evidence point rather than recycling the earlier conclusion. Please start with the decision we need to make, then show whether the available evidence is strong enough to support it.

Please prepare a model-ready table, data dictionary and an honest baseline. The output must help us decide which alert features should be corrected, retained or routed elsewhere.

Data available: transaction-level timestamps, channels, amounts, statuses and error context; ATM attempts, host responses, PIN attempts, blocked-card state and latency; customer contacts, complaints and suggestions; monthly account snapshots, status events, limits, product enrolments and signatories.

Please state the limitation plainly: A plausible explanation is not automatic clearance; investigators still own the decision.

Thanks
