Are failed ATM attempts forming an attack sequence? - 2023 control review

Hi team,

Cyber wants to know whether repeated PIN failures, balance enquiries and cash attempts form recognisable sequences before a card is blocked.

This has returned because the previous answer was useful but not strong enough to become a standing rule. Use September 2023 as the new evidence point rather than recycling the earlier conclusion. Please start with the decision we need to make, then show whether the available evidence is strong enough to support it.

Can you test these explanations rather than choosing one at the start?

- specific terminals see repeated card testing
- normal forgotten-PIN behaviour dominates
- a balance enquiry followed by rapid withdrawals marks higher risk

The decision is which sequences should become monitoring rules and which would create unacceptable false positives. Please give us a Power BI page with drill-through to a reproducible case list.

You should be able to build the evidence from ATM attempts, host responses, PIN attempts, blocked-card state and latency; transaction-level timestamps, channels, amounts, statuses and error context; monthly account snapshots, status events, limits, product enrolments and signatories. There is no CCTV, device fingerprint or complete card-network feed, so classify behavioural patterns rather than confirmed attacks.

Thanks
