Are we collecting on the wrong day for the customer's cash flow? - 2023 control review

Hi all,

I may be joining dots that do not belong together, so please challenge the premise.

Payments wants to test whether collection timing, rather than inability to pay, explains repeat debit-order failure. The discussion is currently being driven by anecdotes, and the teams involved are describing the same customers differently.

Could the answer be that retry timing improves success? Or are we actually seeing that fixed collection rules work differently across customer groups? I also do not want us to miss the possibility that collection before regular inflow drives failure.

This has returned because the previous answer was useful but not strong enough to become a standing rule. Use September 2023 as the new evidence point rather than recycling the earlier conclusion. The practical decision is whether to test alternative debit dates or change retry logic. Please send a short decision pack with no more than five slides and an attached evidence table; I need the exceptions and counter-examples, not only an average.

Work from debit-order mandates, collection dates, suspensions and cancellations; transaction-level timestamps, channels, amounts, statuses and error context; the latest closed loan files available by the request date, including affordability, pricing and origination risk fields; collections cases, promises to pay and recovery payments. Regular inflows are inferred from transaction patterns; no verified payroll calendar is available.

Regards
