Follow-up: who self-cures, and who is harmed by unnecessary contact?

Hi team,

Collections wants a prioritisation model, but validation must separate default risk from the effect of different contact strategies.

This has returned because the previous answer was useful but not strong enough to become a standing rule. Use December 2023 as the new evidence point rather than recycling the earlier conclusion. Several teams are reporting more failed or retried activity than they expected, but they do not agree on the cause. The first extracts did not reconcile, which means source precedence and exclusions must be part of the answer.

Can you test these explanations rather than choosing one at the start?

- contact channel changes promise-kept rates
- high-risk customers need tailored arrangements rather than more attempts
- some customers self-cure without intervention

The decision is whether a model can support treatment allocation and what experiment is needed next. Please give us a model-ready table, data dictionary and an honest baseline.

You should be able to build the evidence from collections cases, promises to pay and recovery payments; customer contacts, complaints and suggestions; transaction-level timestamps, channels, amounts, statuses and error context; the latest closed loan files available by the request date, including affordability, pricing and origination risk fields. Observational data cannot prove treatment causality; recommend a controlled test where appropriate.

Thanks
