## The retry pattern needs to be separated from demand - 2024 control review

---

Team,

Before this becomes another standing report, can we answer the real question?

During service degradation, repeated attempts can inflate volume and obscure the number of customers actually affected. The possible stories are that channel switching follows a timeout, that customers retry the same action within minutes, or that automatic retry and human retry are being mixed.

This has returned because the previous answer was useful but not strong enough to become a standing rule. Use July 2024 as the new evidence point rather than recycling the earlier conclusion. Please start with the decision we need to make, then show whether the available evidence is strong enough to support it.

Please prepare a one-page finding note plus the underlying CSV for our own review. The output must help us decide how monitoring should count affected customers and when retry controls should activate.

Data available: transaction-level timestamps, channels, amounts, statuses and error context; ATM attempts, host responses, PIN attempts, blocked-card state and latency.

Please state the limitation plainly: Without application session IDs, use account, amount, channel and time proximity as an explicit matching heuristic.

Thanks
