Cross-channel anomalies without labelling customers as fraudsters - 2024 control review

Hi all,

I may be joining dots that do not belong together, so please challenge the premise.

A rapid move between transaction channels can indicate account takeover, customer recovery behaviour or an operational workaround. There is no confirmed problem yet; this is a request to test an assumption before it becomes policy.

Could the answer be that security events drive channel switching? Or are we actually seeing that newly opened accounts have a different normal pattern? I also do not want us to miss the possibility that service failure explains most switches.

This has returned because the previous answer was useful but not strong enough to become a standing rule. Use October 2024 as the new evidence point rather than recycling the earlier conclusion. The practical decision is which patterns belong in cyber monitoring and which belong in service monitoring. Please send a short decision pack with no more than five slides and an attached evidence table; I need the exceptions and counter-examples, not only an average.

Work from transaction-level timestamps, channels, amounts, statuses and error context; ATM attempts, host responses, PIN attempts, blocked-card state and latency; monthly account snapshots, status events, limits, product enrolments and signatories; customer contacts, complaints and suggestions. No device identity or IP address is available; do not describe a new channel as a new device.

Regards
