Security control or false-positive factory? - 2025 control review

Team,

Before this becomes another standing report, can we answer the real question?

Card blocking protects customers, but repeated legitimate attempts and later complaints may reveal controls that are too blunt. The possible stories are that ordinary PIN errors create avoidable blocks, that customers receive inconsistent recovery paths, or that blocked cards follow genuinely unusual sequences.

This has returned because the previous answer was useful but not strong enough to become a standing rule. Use May 2025 as the new evidence point rather than recycling the earlier conclusion. Please start with the decision we need to make, then show whether the available evidence is strong enough to support it.

Please prepare a control view with the exceptions, owner and reason each item was included. The output must help us decide where thresholds, escalation or customer communication should change.

Data available: ATM attempts, host responses, PIN attempts, blocked-card state and latency; transaction-level timestamps, channels, amounts, statuses and error context; monthly account snapshots, status events, limits, product enrolments and signatories; customer contacts, complaints and suggestions.

Please state the limitation plainly: Do not label a block as incorrect without the rule decision and investigation outcome.

Thanks
