Validate the treatment strategy, not only the risk rank - 2025 control review

Hi all,

I may be joining dots that do not belong together, so please challenge the premise.

Collections wants a prioritisation model, but validation must separate default risk from the effect of different contact strategies. Please start with the decision we need to make, then show whether the available evidence is strong enough to support it.

Could the answer be that contact channel changes promise-kept rates? Or are we actually seeing that some customers self-cure without intervention? I also do not want us to miss the possibility that high-risk customers need tailored arrangements rather than more attempts.

This has returned because the previous answer was useful but not strong enough to become a standing rule. Use May 2025 as the new evidence point rather than recycling the earlier conclusion. The practical decision is whether a model can support treatment allocation and what experiment is needed next. Please send a working Excel file with the exception population and clear columns; I need the exceptions and counter-examples, not only an average.

Work from collections cases, promises to pay and recovery payments; customer contacts, complaints and suggestions; transaction-level timestamps, channels, amounts, statuses and error context; the latest closed loan files available by the request date, including affordability, pricing and origination risk fields. Observational data cannot prove treatment causality; recommend a controlled test where appropriate.

Regards
