One failed payment may be generating five technical events - 2025 control review

Hi,

This came up in a working session and nobody had the same definition.

During service degradation, repeated attempts can inflate volume and obscure the number of customers actually affected.

I do not want a dashboard that simply counts the outcome. Start with the competing explanations: automatic retry and human retry are being mixed; customers retry the same action within minutes; or channel switching follows a timeout.

Please start with the decision we need to make, then show whether the available evidence is strong enough to support it. This has returned because the previous answer was useful but not strong enough to become a standing rule. Use December 2025 as the new evidence point rather than recycling the earlier conclusion.

What we need to decide is how monitoring should count affected customers and when retry controls should activate. Please bring a short decision pack with no more than five slides and an attached evidence table, including a few cases we can trace from source to conclusion.

The available evidence is transaction-level timestamps, channels, amounts, statuses and error context; ATM attempts, host responses, PIN attempts, blocked-card state and latency. Without application session IDs, use account, amount, channel and time proximity as an explicit matching heuristic.

Thank you
